

Regulatory programmes lose identity to lineage state in SCLC tumours

Replicated across two independent patient cohorts (160 tumours). Regulons were built from paralog-resolved cell-line chromatin and are internally valid there; in tumours their scores are explained by neuroendocrine lineage state, not by the paralog's own expression.

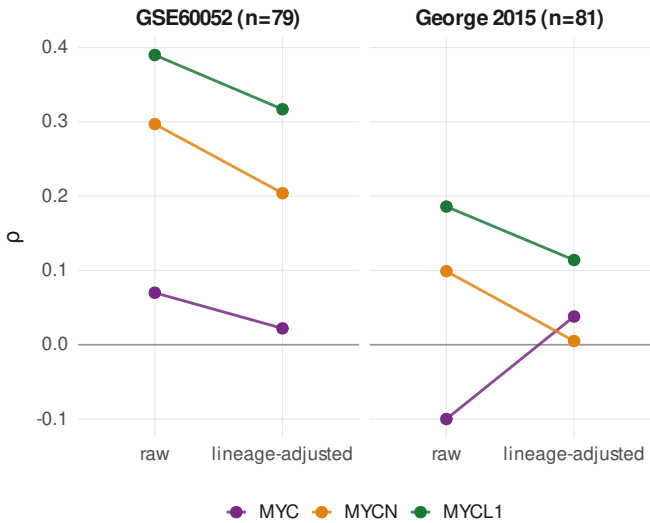

A · Lineage explains the scores, not the paralog

unique variance explained, after removing the other term

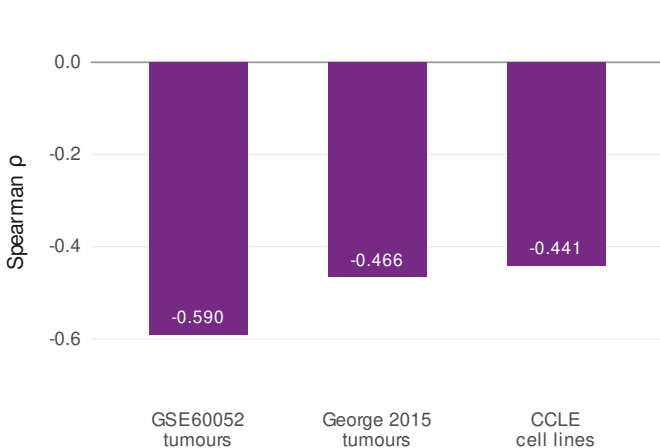

B · The association collapses after adjustment

Spearman rho, regulon score vs its own paralog's expression

C · The mechanism, reproduced three times

MYC expression vs neuroendocrine score (Ireland et al. 2020)

D · The diagonal does not dominate

regulon score vs each paralog's expression (GSE60052); boxed cells are the expected self-associations
