

Functional evidence supports the regulon genes collectively, not any one parallel

Dependency is not expression, so it escapes the lineage confound that removed the transcriptional domain — but on 4–5 selective genes per regulon it cannot separate the paralogs. Of four planned evidence domains, two are admitted and one attributes evidence to a paralog.

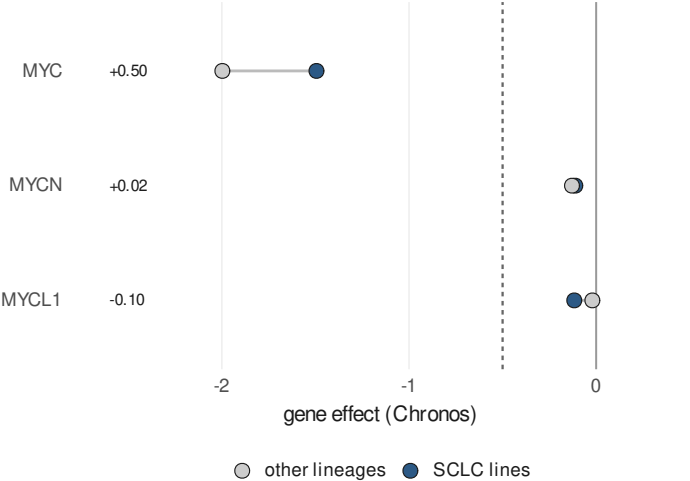

A · Real pooled, not separable per paralog

SCLC-selective dependency among regulon genes
odds ratio, 95% CI, log scale

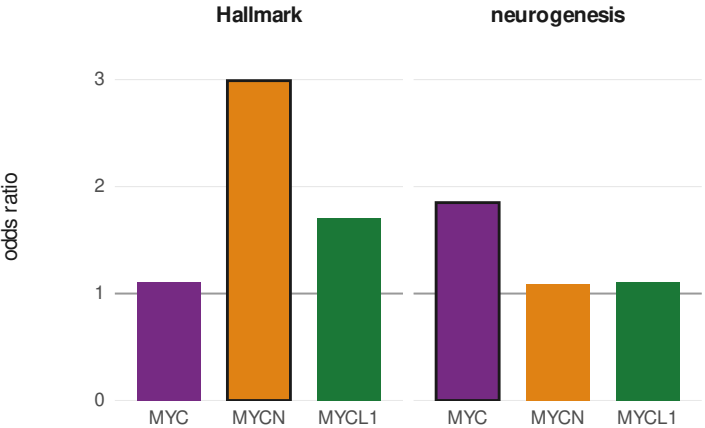

B · No paralog is selectively essential

mean CRISPR gene effect; dashed line = -0.5
labels give SCLC minus other lineages

C · MYC is neurogenesis-weighted; MYCN is not

regulon-gene enrichment; outlined bar = assigned programme

D · 2 of 4 domains admitted, 1 paralog-resolved

paralog attribution rests on chromatin alone
